Attorney Docket No. 040071-510 -27-Patent

ABSTRACT

[0068] Method, apparatus, and system for synchronization in radio communication systems are presented. The method includes the steps of encapsulating symbols in an information stream then modulating the stream. The modulated information stream is then sent over a communication channel at a first robustness level, and the level of robustness of the information stream is then reduced to a second robustness level according to a predetermined function. The modulated information stream is received from the communication channel. The information stream is then demodulated after a first number of symbols have been received, wherein the first number of symbols is less than a second number of symbols that would have to be received to demodulate a corresponding information stream sent over the communication channel only at the second robustness level.
